

Web and Database Programming

Assignment 1 - Kickstarting Your Project

This assignment will help you begin building your project. You'll be designing a full stack web application based on an idea of your choice. If you're unsure what to create, some simple ideas include a to-do list, a note-taking app, or the beginning of a social media site.

Your application should include two entities (such as users and posts, or notes and tags) with basic CRUD functionality (Create, Read, Update, and Delete); Don't worry, you'll learn what this means later in the course!

If you choose a more complex idea, like a social media platform, keep the functionality for your project submission as simple as possible. By the end of the course, your app only needs to support user registration, login, and the ability to create, edit, update, and delete an item (like a post, note, or task), depending on the type of app you build.

The goal of this project is to help you understand how full stack applications work, how to design them, and how to implement basic features. Focus on simplicity; you can always build on it after the course ends!

1. Download a text editor of your choice. I recommend Visual Studio Code since it is the one I will be using. The link to download Visual Studio Code: <https://code.visualstudio.com/download>
 2. Download the extension Live Server if you are using Visual Studio Code. Use Live Server as you make changes to your html pages to see updates in real time.
 3. Create a new folder that will hold all of your project files. Be sure to utilize the same folder for any files you create for your project.
 4. Inside your project folder, create a .txt file and write a short description of your project idea. Include the main purpose of the application and a list of key features or functions that users will be able to interact with. Try to be as clear and specific as possible, even if your idea is still in the early stages. Some questions to help guide your write-up:
 - a. What problem does your app solve or what purpose does it serve?
 - b. Who is the intended user?
 - c. What actions will users be able to perform (e.g., sign up, add items, search, comment, etc.)?
- This will help you begin planning your app's structure and functionality before we dive into coding.

5. Inside your project folder, create a folder called **images**. Any images that you decide to add to your web pages should be saved here.
6. Create 3 html files — one for a **register**, **login**, and **post/note/item/etc.** page depending on what you want to create. Eventually, your project should have the ability to login and register a user, and allow a user to create a post/note/item/etc.
 - **IMPORTANT:** Your form DOES NOT have to be functional! This is purely visual for now until we set up the backend.
 - For each page, you must have the starter template (html, head, body, etc. elements). You must also use the **form** element — one form for each page.
 - **Minimum** requirements for the **register** form is to have an input for first name, last name, username OR email, password, and an input for submitting the form. Be sure to use the proper input type (text, password, submit, etc.).
 - **Minimum** requirements for the **login** form is to have an input for either username or email, an input for password, and an input for submitting the form.
 - **Minimum** requirements for the **post/note/item/etc.** form is an input for text and an input for submitting the form.
7. Create a navigation bar using anchor tags that allows you to navigate throughout your site. Make sure the navigation bar is on each page!
8. Compress your project folder into a **zip file** and submit.
